# Introduction to IP Routing

#### **Table of Contents**

d

- Routing Basics
- ► IP Routing Process
- Static and Dynamic Routing

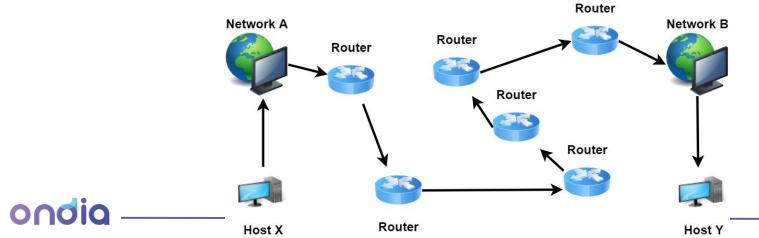

- O
- IP routing is the process of sending packets from a host on one network to another host on a different remote network
- This process is usually done by routers
- Routers use routing tables
- Routers don't really care about hosts—they care only about networks and the best path to each network

To be capable of routing packets, a router must know at least the following information:

- Destination network address
- Neighbor routers from which it can learn about remote networks
- Possible routes to all remote networks
- The best route to each remote network
- How to maintain and verify routing information

d

Each router maintains a routing table

Routing Tables: Public

- Routing table is used to determine the path to the destination network
- Each routing table consists of:
  - Network destination and subnet mask
  - Remote router IP address of the router

[Comware] display ip routing-table

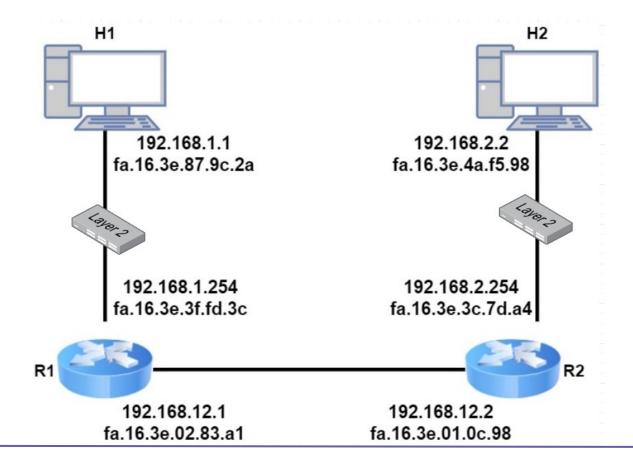

Outgoing interface

```

                                                              GigabitEthernet0/2
```

#### <u>R2</u>

Build a new frame and send to H2

Source: Destination: Source: Destination: 192.168.1.1 Destination: Data

#### <u>H2</u>

- Checks the FCS
- Finds its own MAC address as the destination MAC address
- De-encapsulates the IP packet from the frame
- Finds its own IP address as the destination in the IP packet

The host has a simple decision to make:

- Is the destination on the local network?
  - Check ARP table for **destination** IP address, if empty, send an ARP request.
- Is the destination on a remote network?
  - Check ARP table for **default gateway** IP address, if empty, send an ARP request.

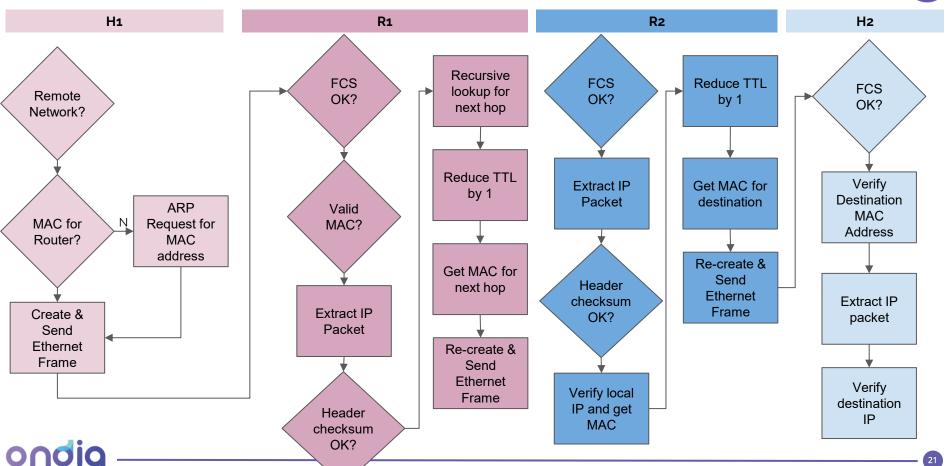

The router has to perform a number of tasks:

- When it receives an Ethernet frame, checks if the FCS is correct. If not, drops the frame
- Checks if the destination address of the frame is:
  - destined to router's MAC address
  - destined to a broadcast address of the network router's interface is in
  - destined to a multicast address that the router listens to
- De-encapsulates the IP packet from the frame, discard the Ethernet frame
- Looks for a match in the routing table for the destination IP address, figures
  out what the outgoing interface and optionally, the next hop IP address is
- Decreases the TTL field in the IP header, recalculates the header checksum
- Encapsulates the IP packet in a new Ethernet frame
- Checks the ARP table for the destination IP address or next hop IP address
- Transmits the frame

#### ►IP Routing Flow Chart - Remote Network

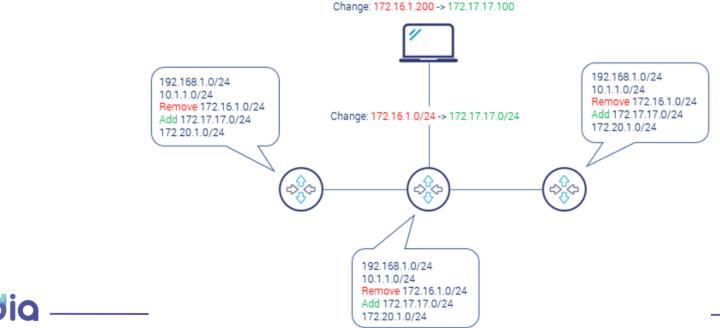

d

- How routers know the IP destinations?
- In static routing (or non-adaptive) routing, tables created and updated manually

- In dynamic routing (or adaptive) routing, tables created and updated automatically using routing protocols
- Dynamic routing is used in larger networks
- Finds the optimal route (fastest path)
- Reacts to topology changes and failures, recalculates optimal path 1.

Static	Dynamic	
Routes are user defined	Routes are updated according to the topology	
Does not use complex routing algorithms	Uses complex routing algorithms	
Provides high or more security	Provides less security	
Manual	Automated	
Implemented in small networks	Implemented in large networks	
Additional resources are not required	Additional resources are required
